

## **N<sub>2</sub>O emissions in China from 1978 to 2008 by F ZHOU**

Abstract: Nitrous oxide (N<sub>2</sub>O) emissions from China have received increasing attention because of its importance on global climate forcing. A new and high-resolution N<sub>2</sub>O emission inventory (PKU-N<sub>2</sub>O-CHINA) has been developed with the following improvements: (i) All of anthropogenic and natural emission sources were considered excluding LULUCF in IPCC category; (ii) the emission factors (EFs) and the associate parameters were updated to reflect country-specific conditions and spatial heterogeneity; (iii) a 1×1 km gridded map was produced for 2008 based on county-level activity data; (iv) temporal trends were derived for total and each emission source from 1978 to 2008; (v) uncertainties associated with the inventory were quantified. It was estimated that 1762 Gg of N<sub>2</sub>O were emitted in China in 2008, which is lower or slightly lower than that previously reported. Manure management systems (29%) was the largest contributor, following by synthetic fertilizers (20.5%), indirect emission from atmospheric N deposition (10.4%), public electricity and heat production (7.9%), and organic fertilizers (6.9%). By using county-level data directly and regional EFs and parameters, spatial bias in previously national or province-level disaggregation was reduced by 120.7%, resulting mainly from uneven intensities of fertilizer and energy uses within nation or provinces. Total and per-capita emissions increased monotonically and steadily since 1978, while agricultural N<sub>2</sub>O emissions per cereal productivity rapidly fell down after 2003 because of nutrient management implemented and high-yield crop varieties promoted. N<sub>2</sub>O emissions in China would be effectively reduced if improving nutrient or energy use efficiencies as well as shifting human dietary choice with lower per capita calorific intake.

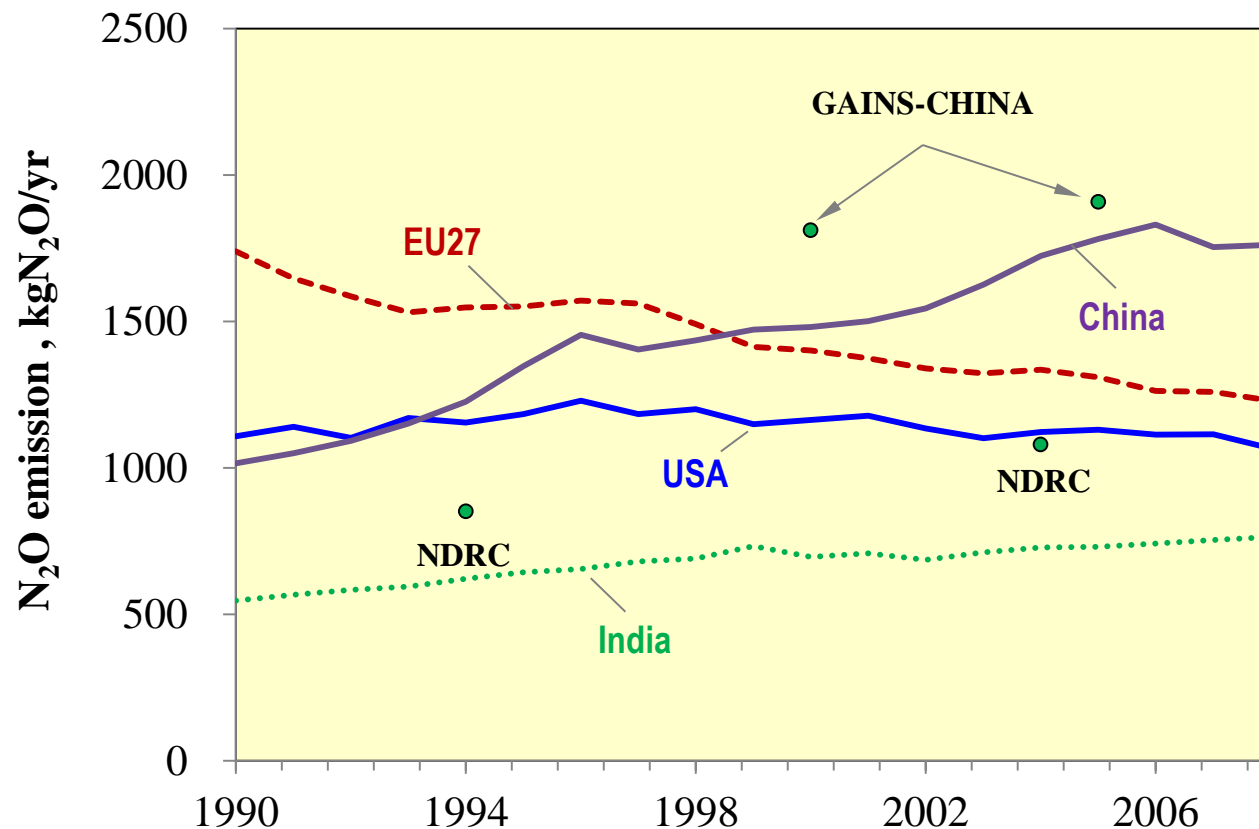

# China's N<sub>2</sub>O emissions (PKU-N2O-CHINA) from 1978 to 2008

F. Zhou, S.L. Piao, P. Ciais, S. Tao, B.G. Li,  
H.Y. Liu, R. Wang, X.H. Wang, S.S. Peng

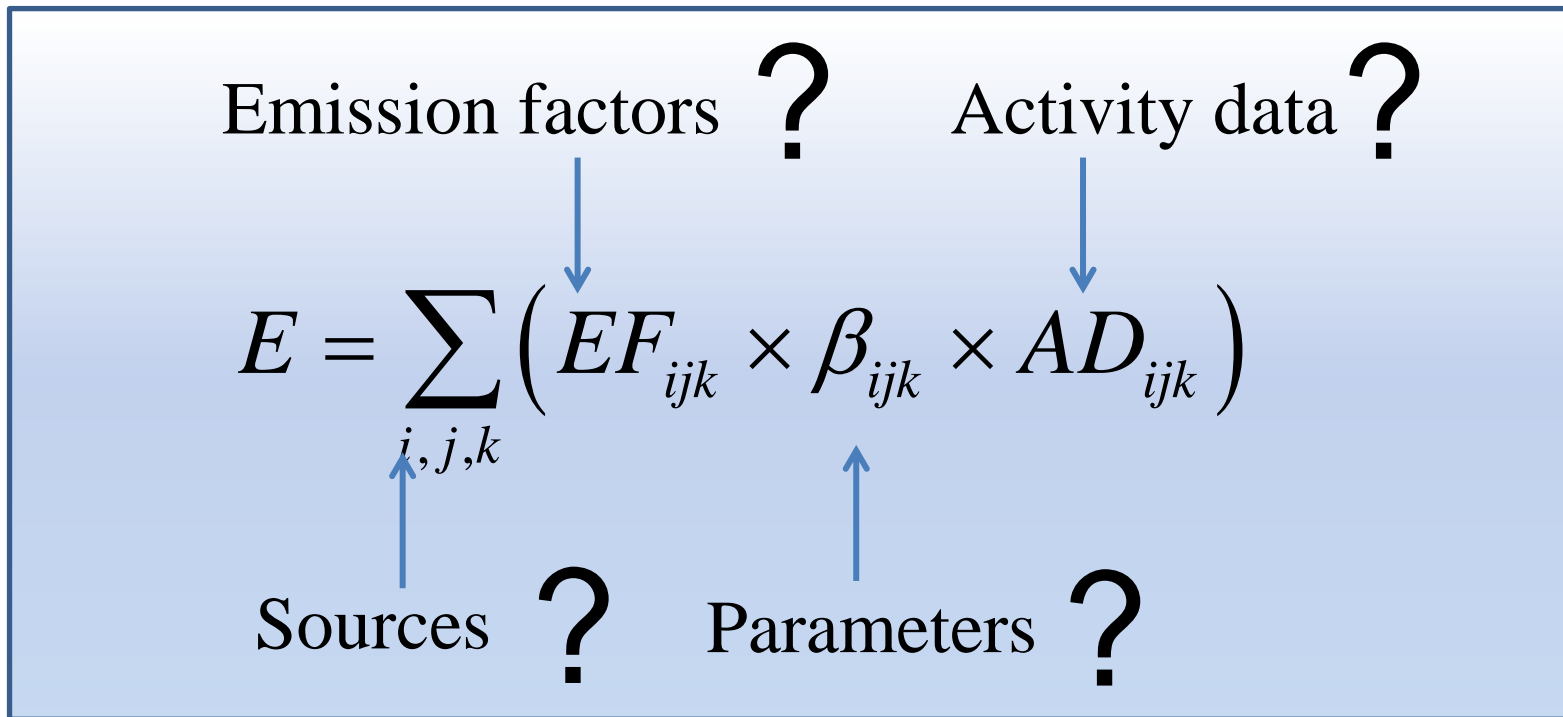

# 1. Motivation

- China contributed ~18% of global anthropogenic N<sub>2</sub>O emissions and becoming largest emitter.
- However, we didn't have our emission inventory...

# 1. Motivation

If we choose bottom-up approach, then

# 1. Motivation

Source<sub>ijk</sub> need to be considered comprehensively

**Agriculture (62.5%)**

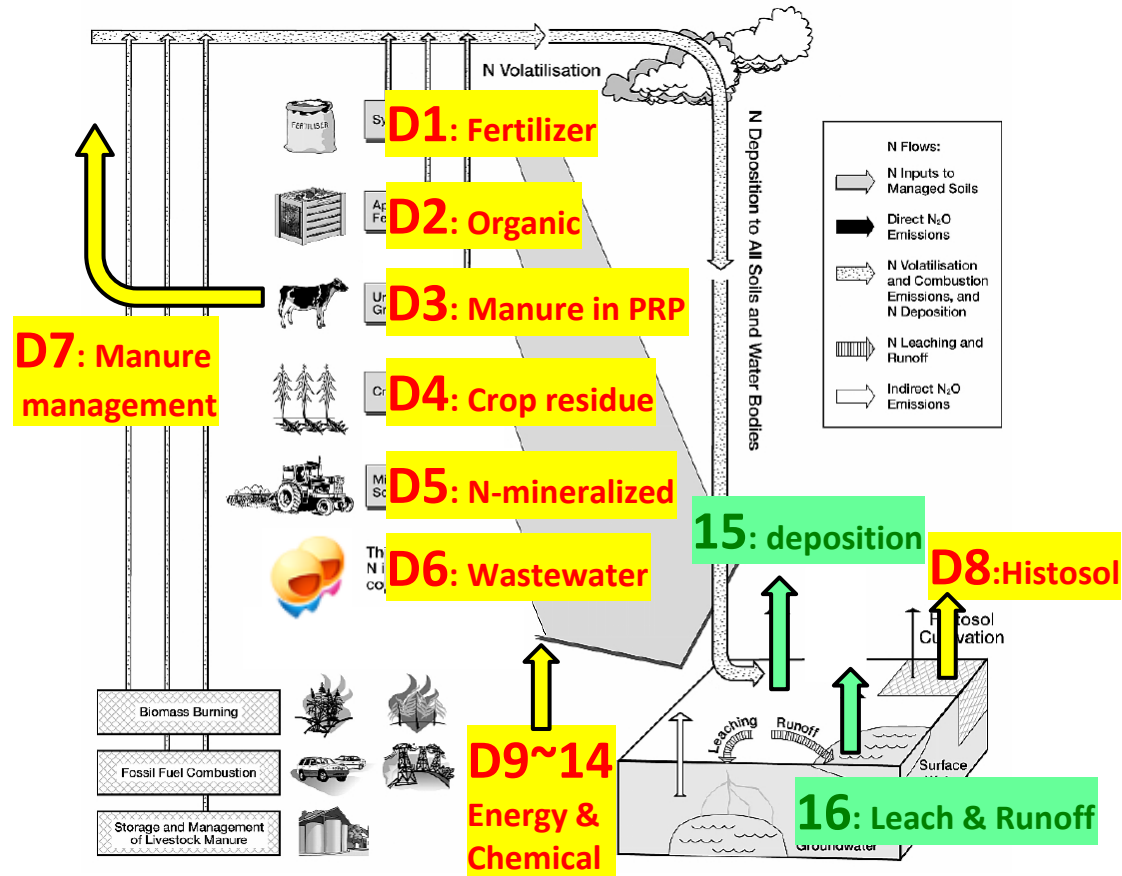

Energy (17.1%)

Industrial (3%)

Waste (5.5%)

**Wildfires (0.3%)**

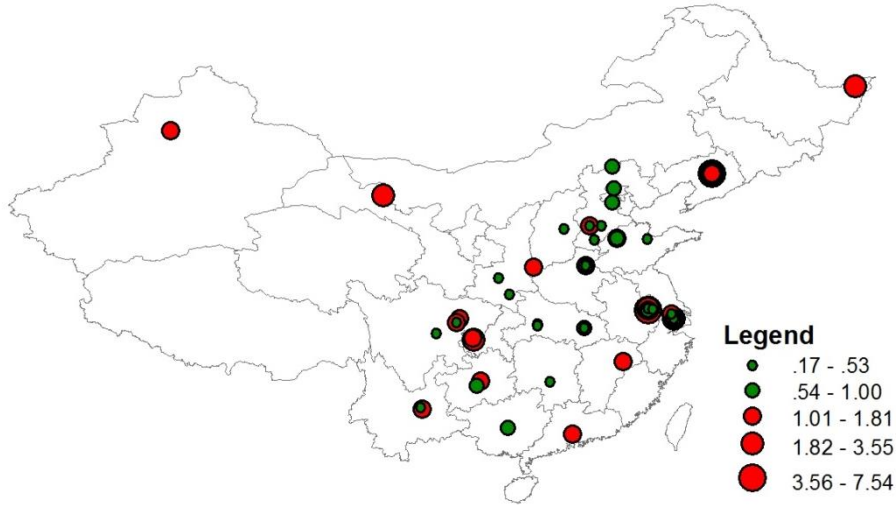

Indirect (11.3%)

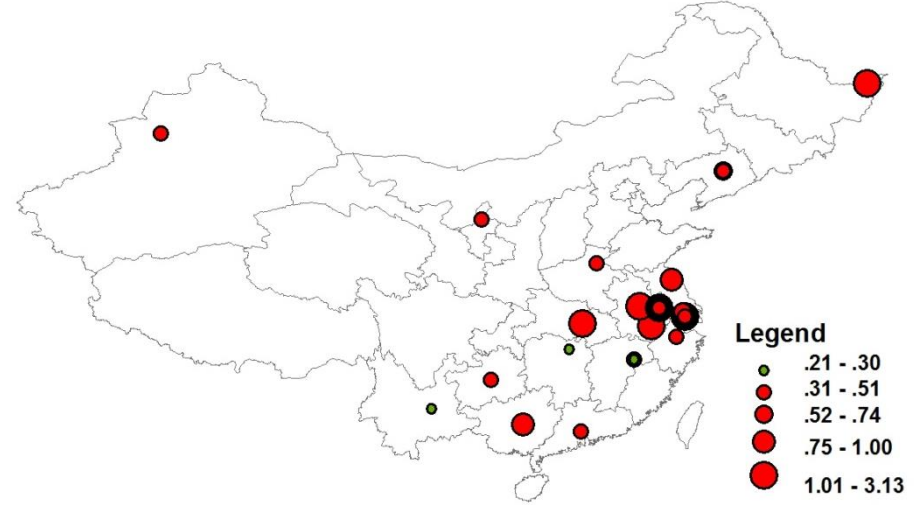

# 1. Motivation

$EF_{ijk}$  need to be country-specific and spatial explicit

$EF_{N_2O}$  for upland

$EF_{N_2O}$  for paddy

*Smaller, 87% of IPCC default*

*Larger, 170% of IPCC*

# 1. Motivation

$\beta_{ijk}$  need to be also country-specific and spatial explicit

## N leaching+runoff ratio

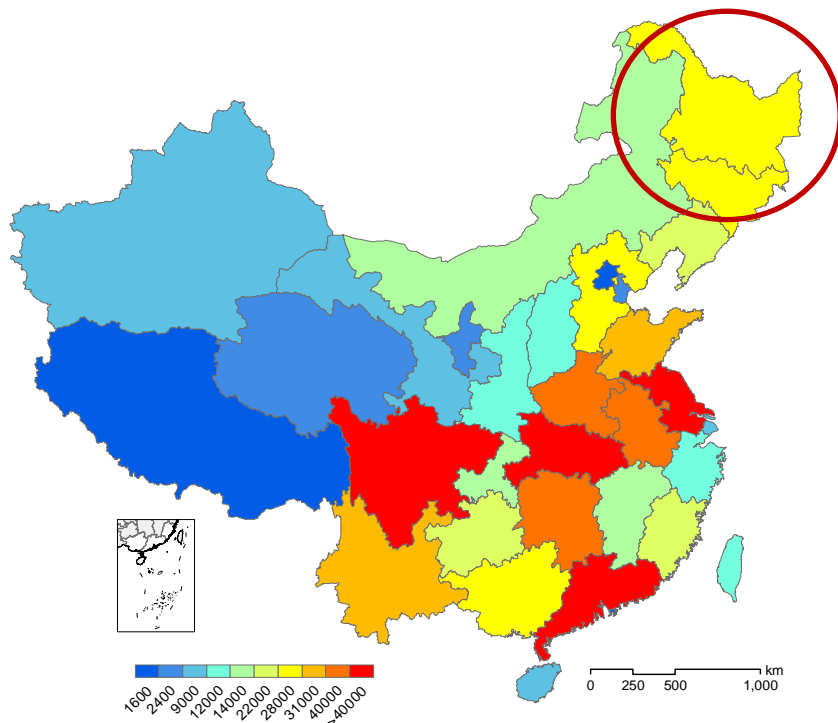

**12% of IPCC defaults**

Crop	Region	IPCC,%	China	SD
1-Paddy	1-Region I	30	8.00	1.37
	2- Region II	30	3.45	0.32
	3- Region III	30	4.13	0.40
	4- Region IV	30	1.68	3.43
	5- Region V	30	1.22	0.90
	6- Region VI	30	1.21	0.47
2-non-paddy	1-Region I	30	4.94	4.62
	2- Region II	30	0.45	0.43
	3- Region III	30	2.49	4.12
	4- Region IV	30	6.26	8.56
	5- Region V	30	7.92	3.53
	6- Region VI	30	0.76	1.59

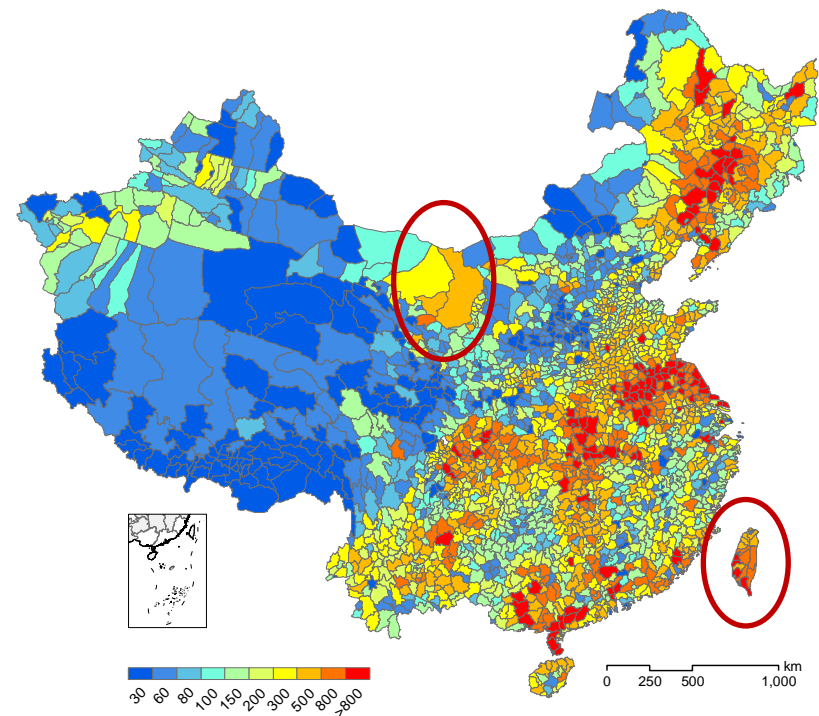

# 1. Motivation

Resolution of  $AD_{ijk}$  need to be as higher as possible for the following spatial allocation

## Fertilizers (Provincial)

## Fertilizers (County)

## 2. Methodology

- So, PKU-N<sub>2</sub>O-CHINA was produced based on following **local, regional and high-resolution** datasets for **all** emission sources

**New** Emission factors **High-resolution** Activity data

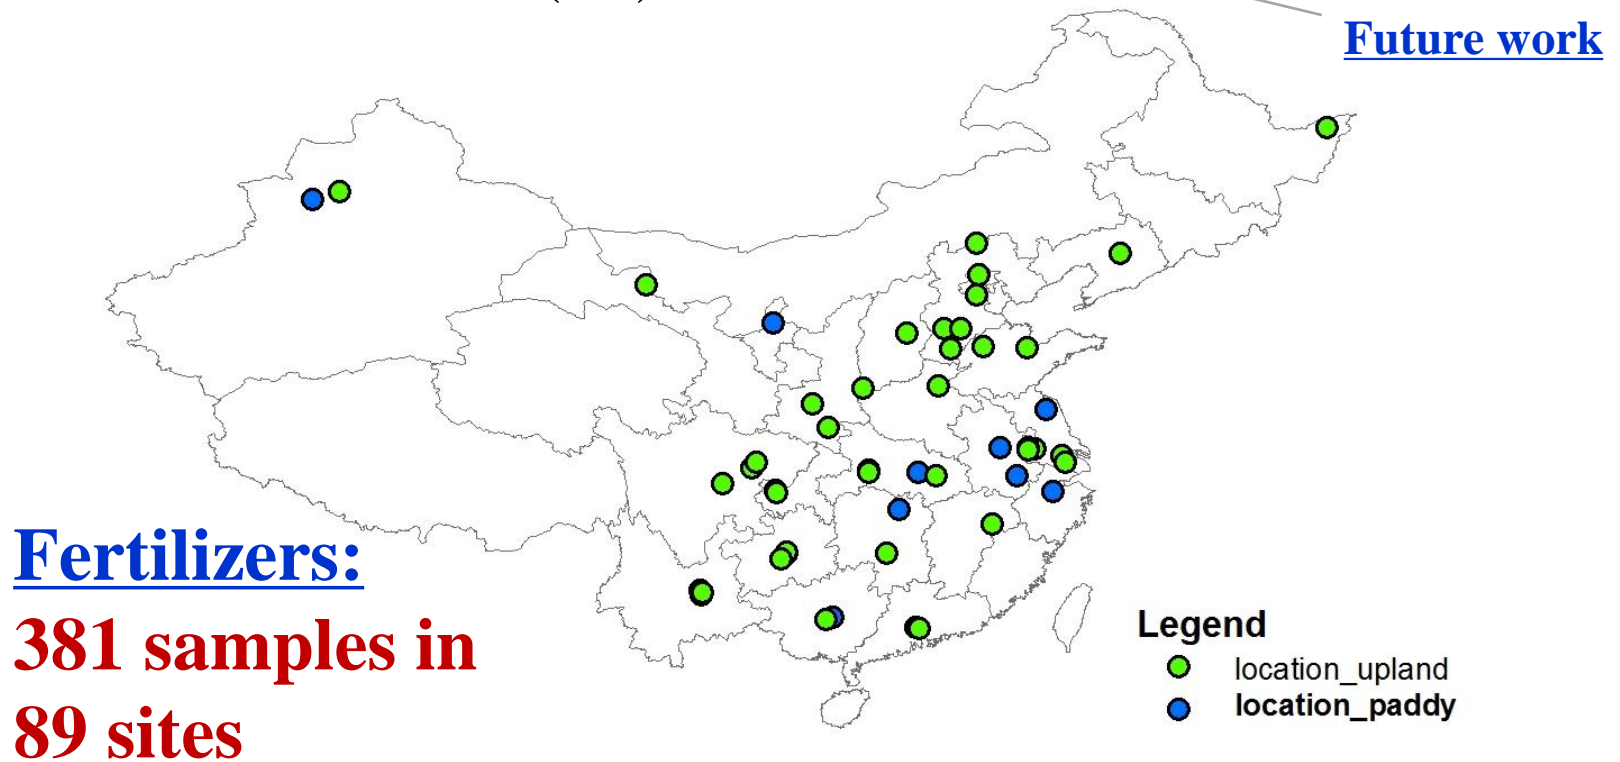

$$E = \sum_{i,j,k} \left( EF_{ijk} \times \beta_{ijk} \times AD_{ijk} \right)$$

**All** Sources

**New and regional** Parameters

## 2. Methodology

- **New  $EF_{N_2O}$**  for fertilizers (381), organic soils (12), manure management systems (**6**), energy (66), indirect emissions (45)

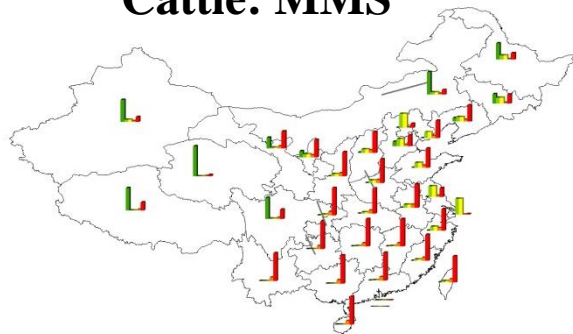

More details can be found in Zhou *et al.* to be submitted

## 2. Methodology

- **New and regional parameters** for **fertilizers, manure management systems, crops, and indirect emissions**

**Cattle: MMS**

**Sheep: MMS**

**Pig: MMS**

**Poultry: MMS**

**N excretion**

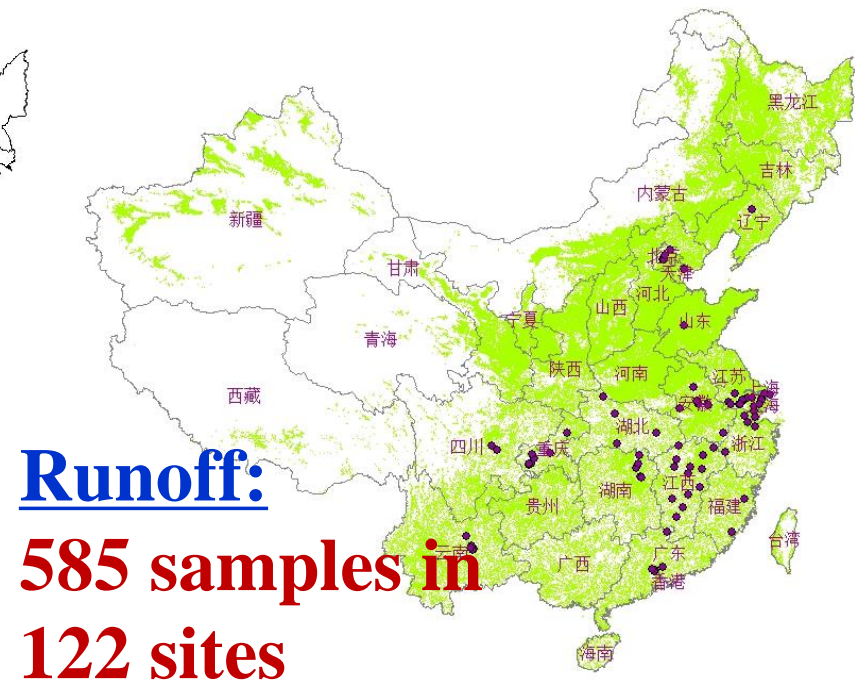

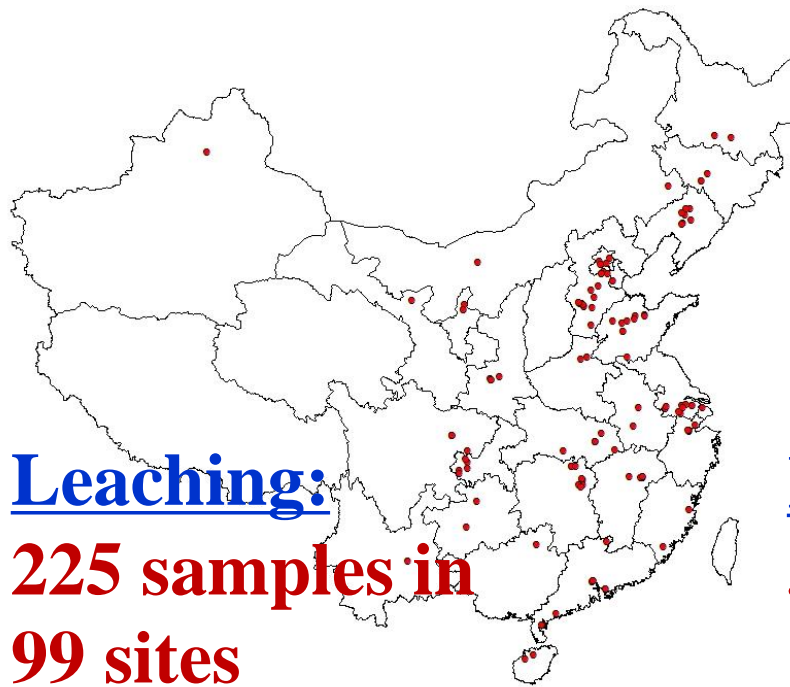

**Residue removed**

M1: Manure in pasture, M2-S: slurry in intensive system, M2-D: drylot in intensive system, M3-S: slurry in free-range system, M3-D: drylot in free-range system

## 2. Methodology

- **New and regional parameters** for fertilizers, manure management systems, crops, and **indirect emissions**

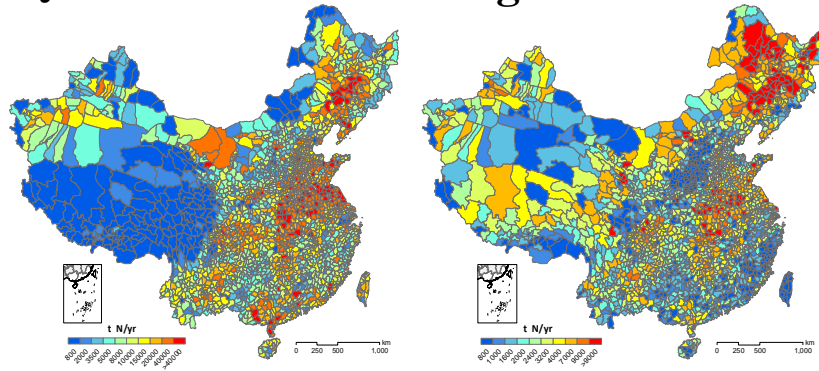

More details can be found in Zhou *et al.* to be submitted

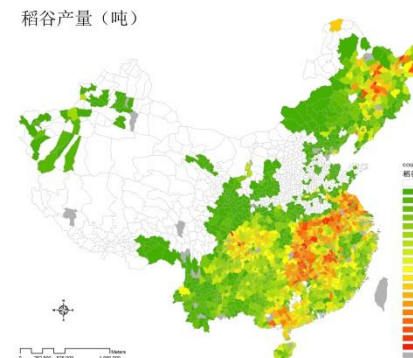

# 2. Methodology

- **High-resolution activity data** for agriculture, energy, wastes, and indirect emissions

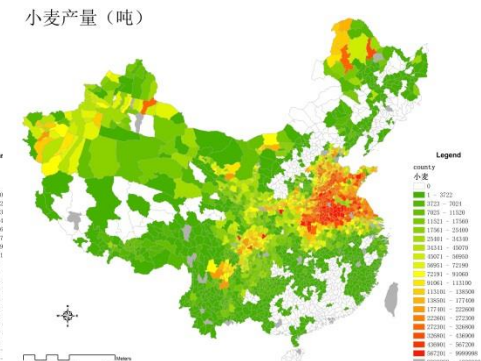

Synthetic fertilizers    Organic fertilizers

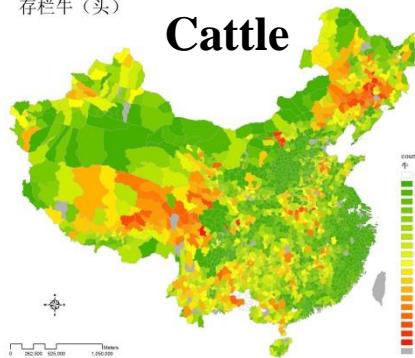

Rice

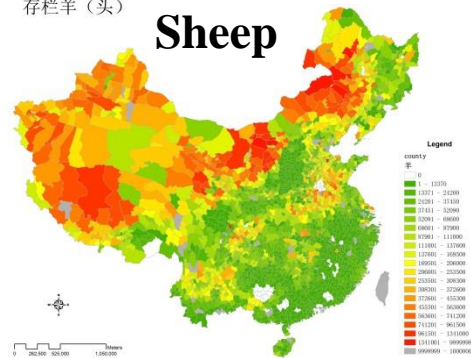

Wheat

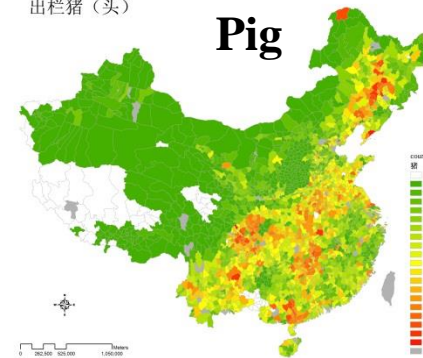

存栏牛 (头)    Cattle

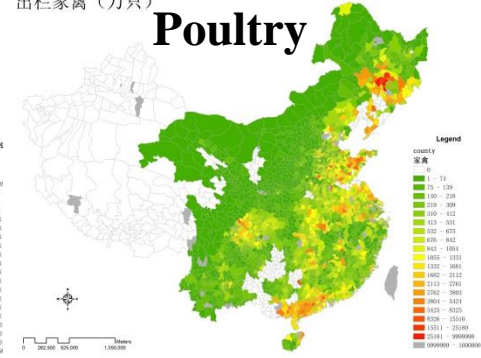

存栏羊 (头)    Sheep

出栏猪 (头)    Pig

出栏家禽 (万只)    Poultry

More details can be found in Zhou *et al.* to be submitted

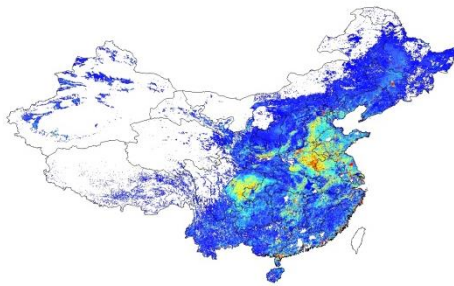

## 2. Methodology

- **High-resolution activity data** for agriculture, energy, wastes, and indirect emissions

Urban Pop

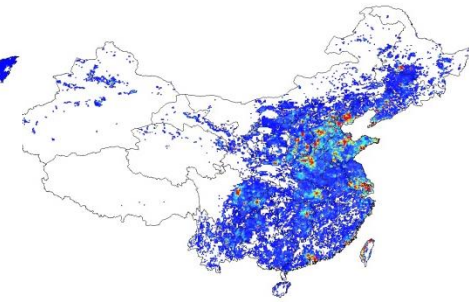

Rural Pop

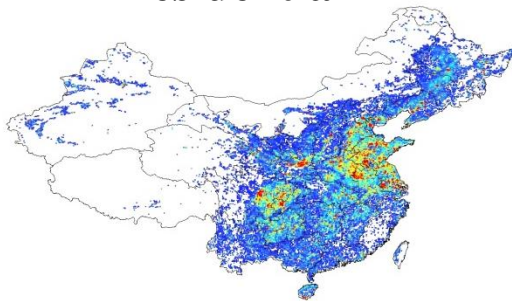

Power plants

Industries

Residential

Road

Railway

**0.1°×0.1°**

More details can be found in Zhou *et al.* to be submitted

## 2. Methodology

- **Spatial allocation** into 1×1 km gridded maps

Source	Allocation proxy
Agriculture	1*1 km cropland
Manure in PRP	1*1 km grassland
Manure management systems	1*1 km rural population
Energy, indirect from N depositions	1*1 km total population
Industries	1*1 km Urban and built-up
Waste	1*1 km urban population

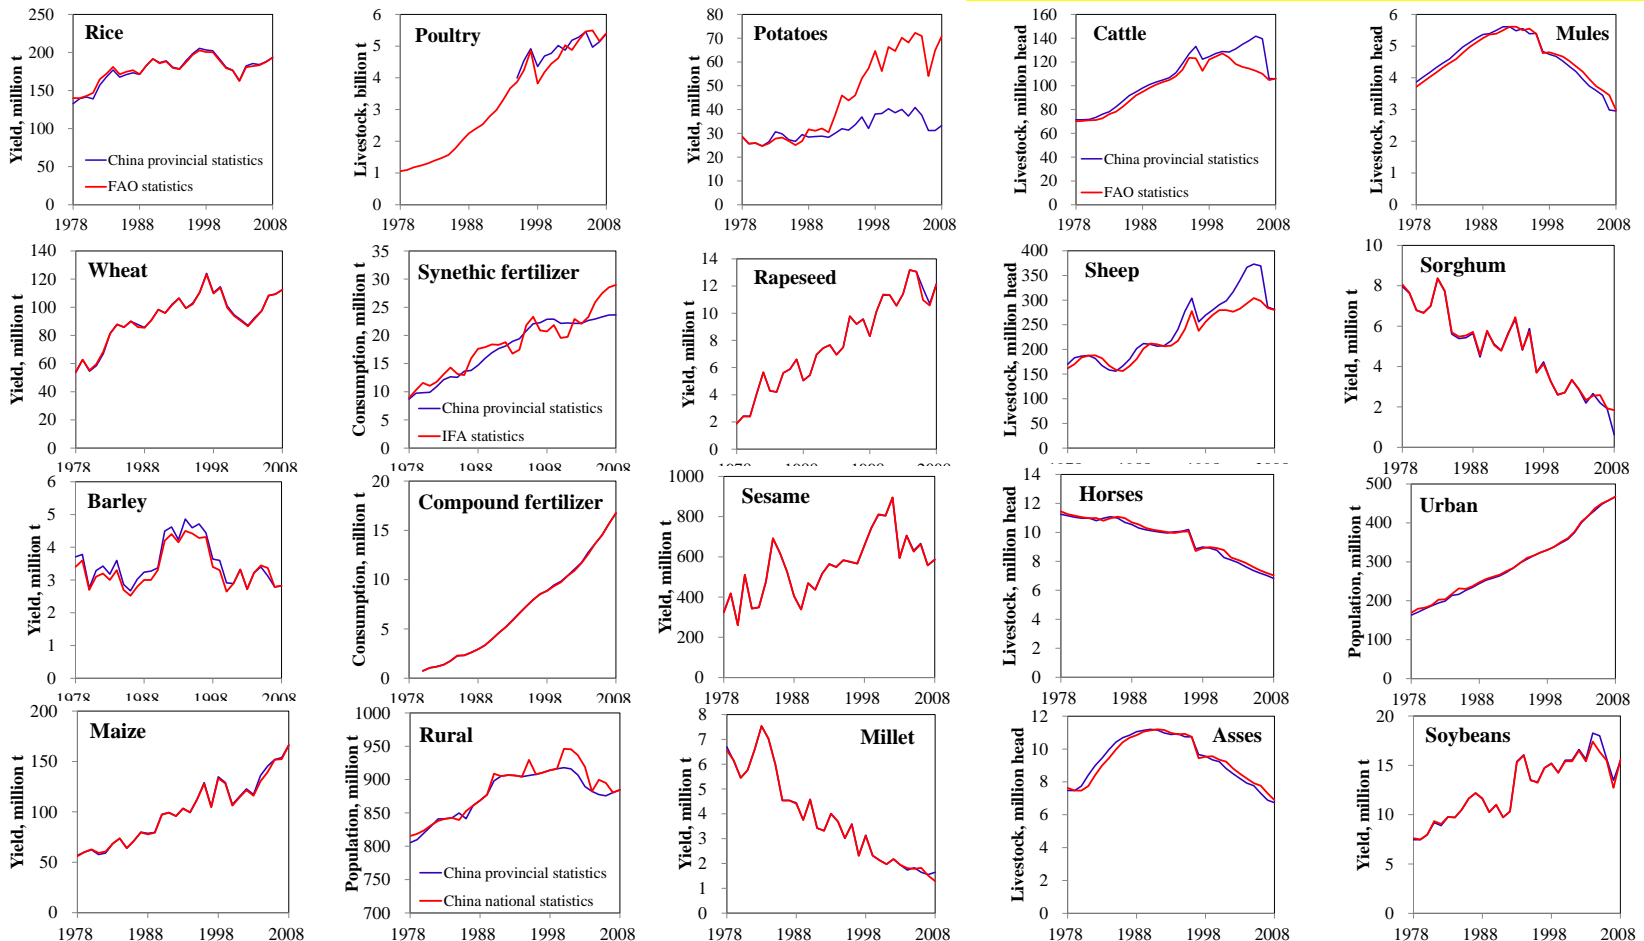

**Base on EDGAR V4.2; Huang et al., 2011; Wang et al., 2012**

# 2. Methodology

- **Uncertainty estimation** through Monte Carlo simulation (1 million runs)

Activity data

Differences with FAO, IEA, IFA

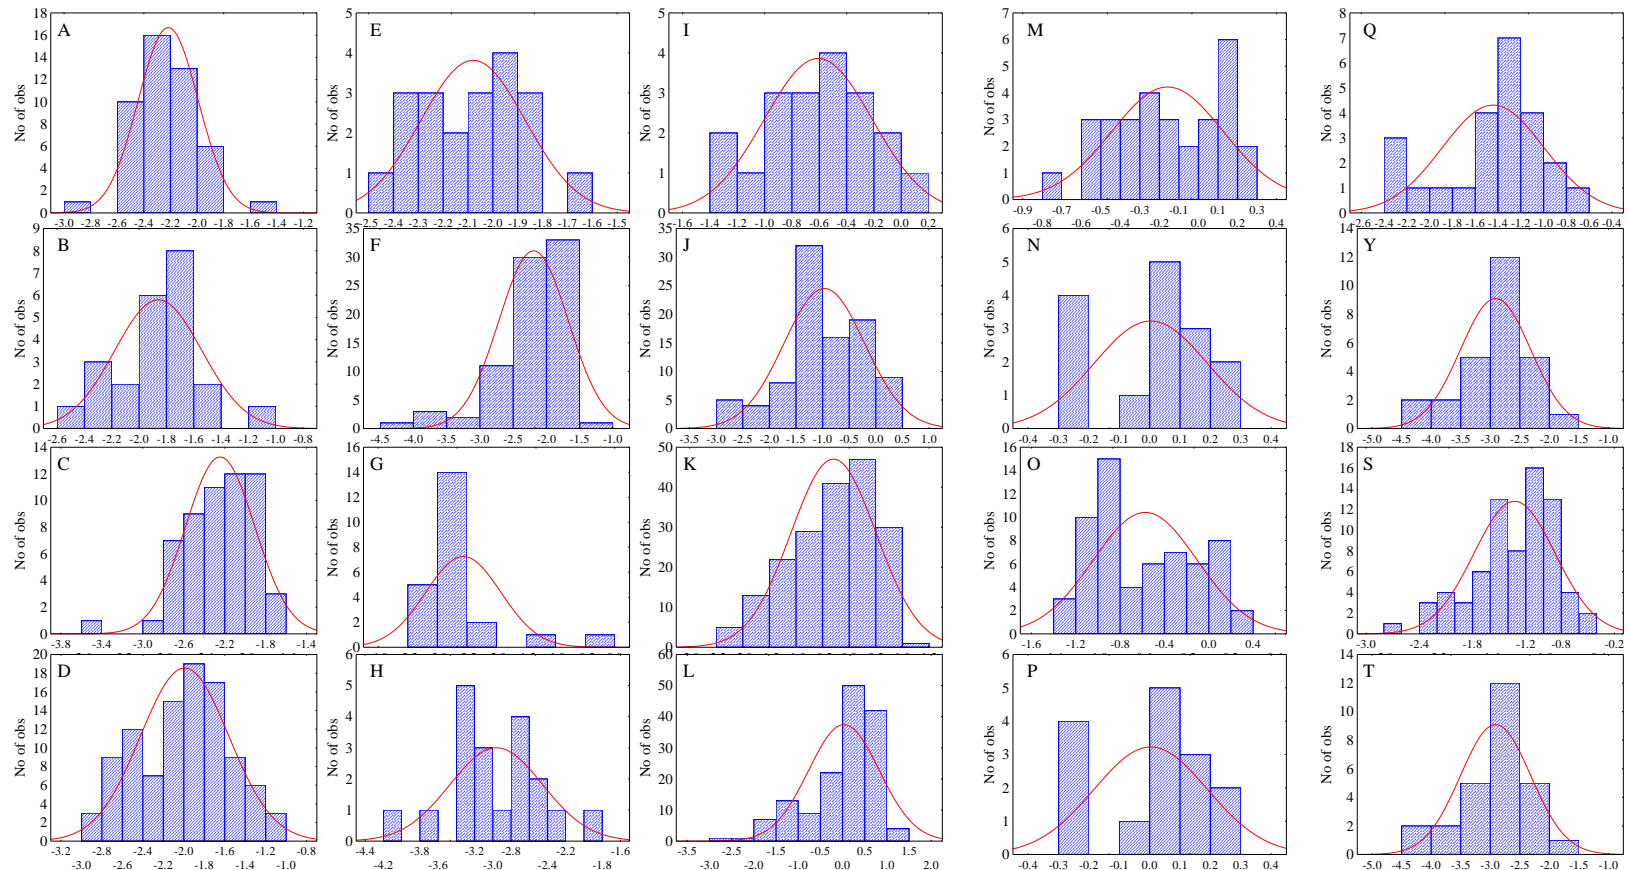

# 2. Methodology

- **Uncertainty estimation** through Monte Carlo simulation (1 million runs)

EF<sub>N2O</sub> and Parameters

Median and SD after log-normal transfer

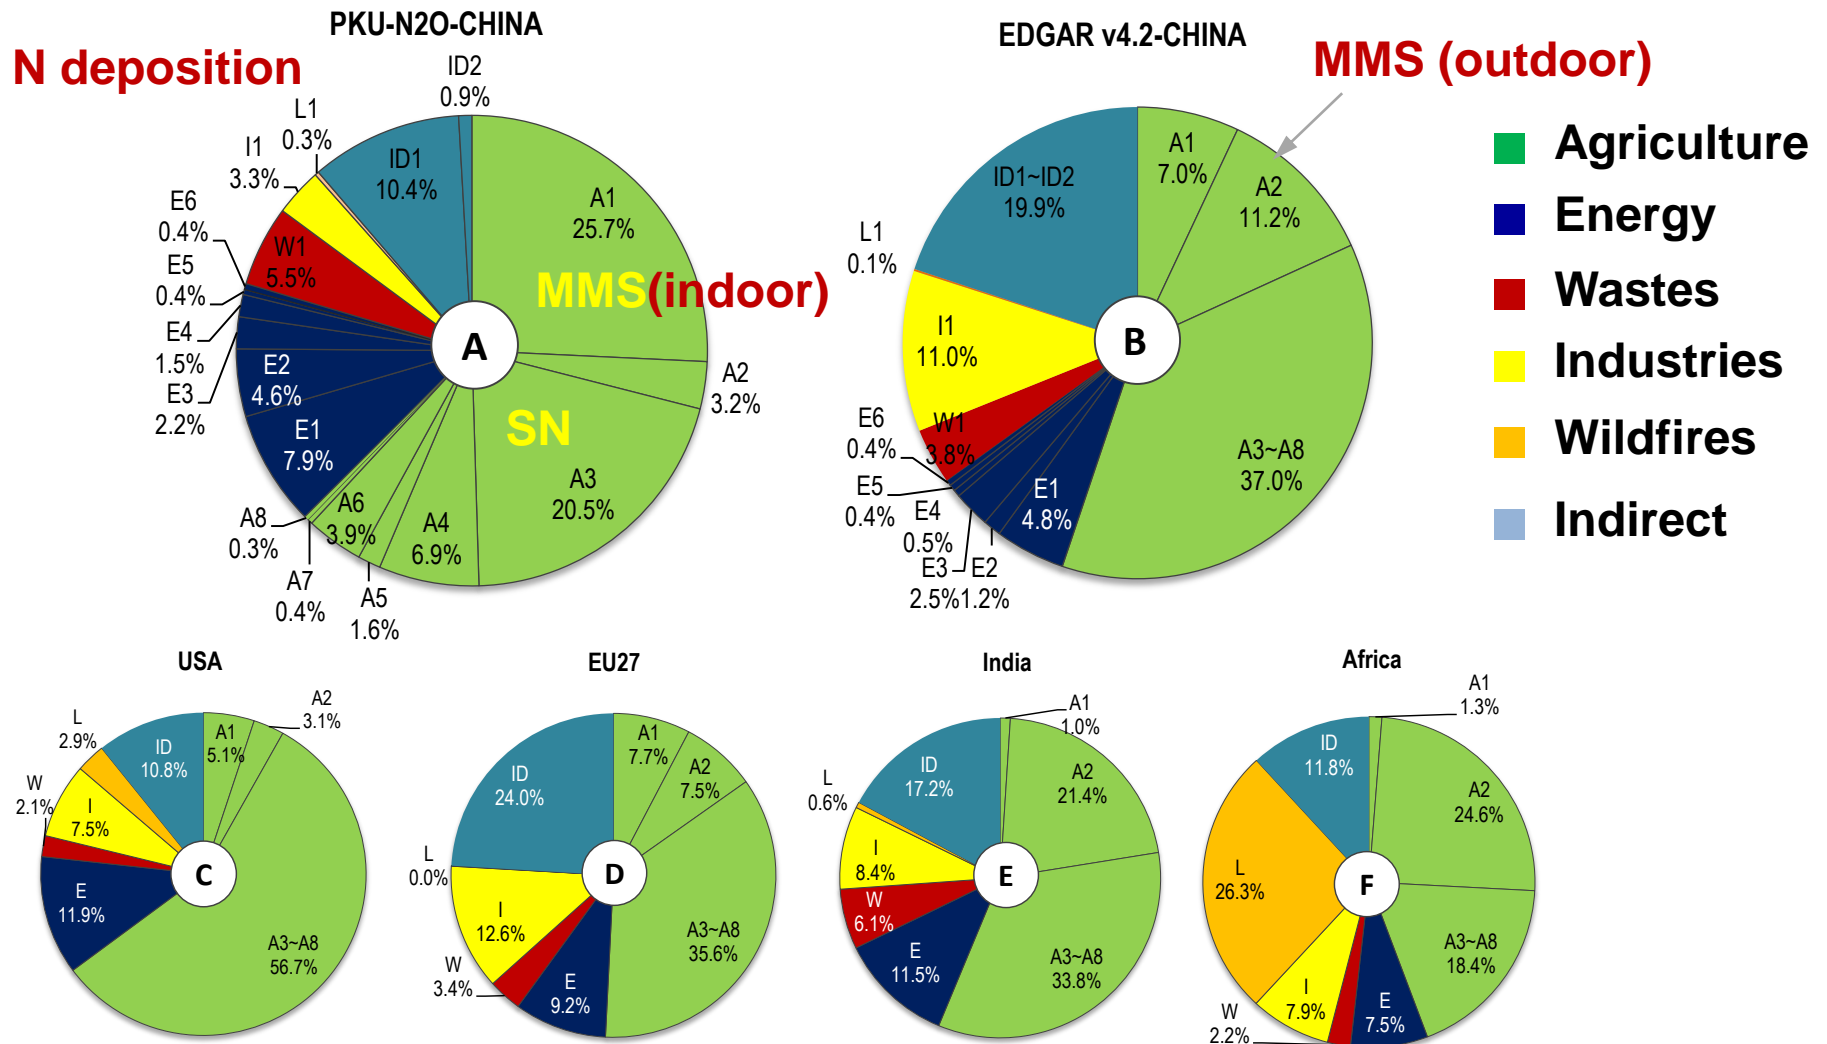

### 3. Total emission and source profile in 2008

- Total emissions (GgN<sub>2</sub>O/yr)

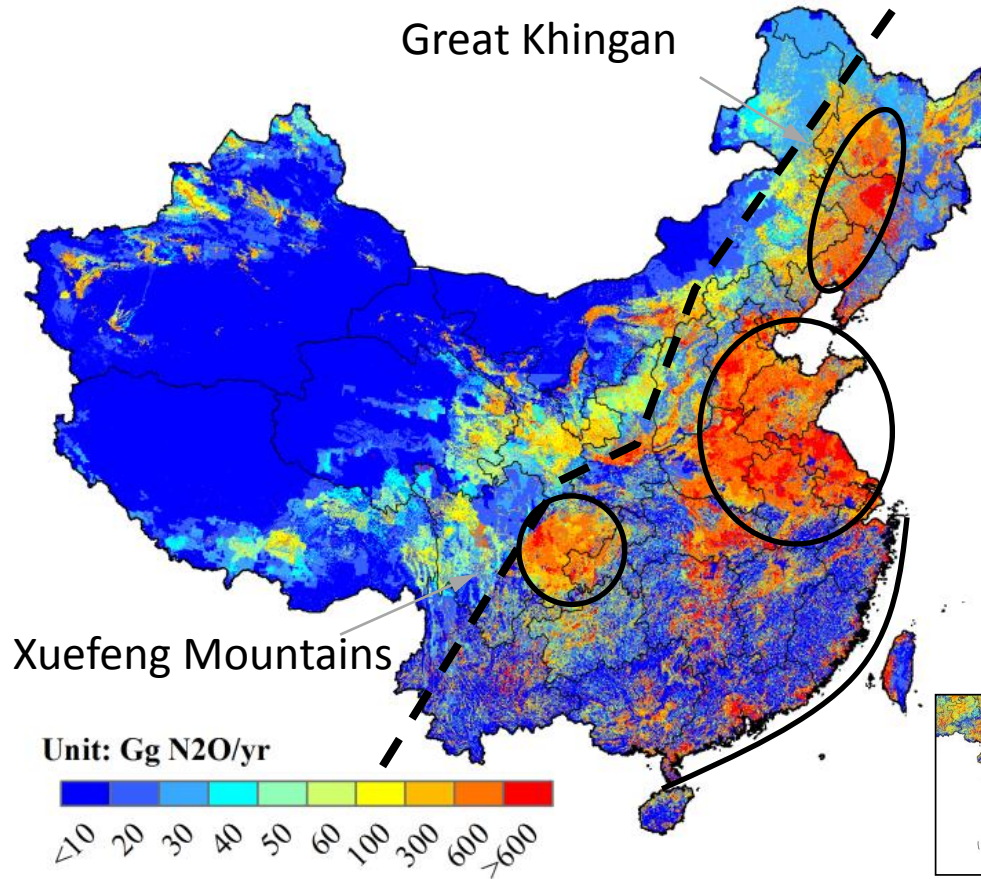

Type	PKU-N2O-CHINA	EDGAR v4.2	GAINS-CHINA
Direct: Agriculture	1102 (62.5%)	981	1697.8
Direct: Energy	300 (17.1%)	176	132.3
Direct: Wastewater	97.6 (5.5%)	68	135.8
Direct: Industry	58.1 (3%)	196	42.5
Wildfires	4.8 (0.3%)	2.4	--
Indirect emissions	199 (11.3%)	354	--
<b>TOTAL</b>	<b>1762 (706~2667)</b>	<b>1778</b>	<b>2008.4</b>

# 3. Total emission and source profile in 2008

- Source profile

# 4. N<sub>2</sub>O spatial pattern in 2008

**East China:**

70%,  $0.43 \text{ Mg}\cdot\text{km}^{-2}\cdot\text{yr}^{-1}$

**West China:**

30%,  $0.078 \text{ Mg}\cdot\text{km}^{-2}\cdot\text{yr}^{-1}$

But, contributions of

**industries** and **indirect** are

near identical with each other

# 4. N<sub>2</sub>O spatial pattern in 2008

(1) agriculture

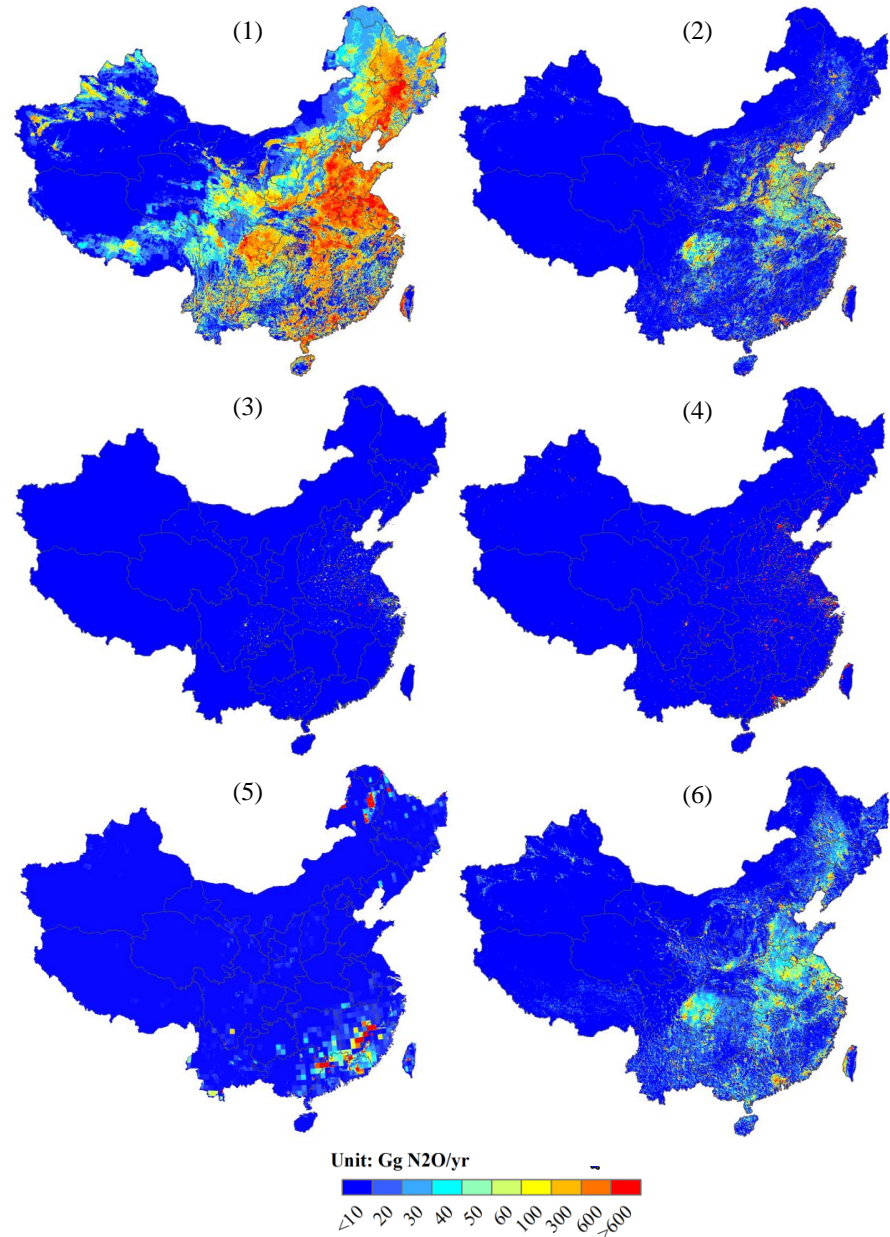

(2) Energy

(3) industrial processes/product use

(4) Waste

(5) Wildfires

(6) indirect emissions

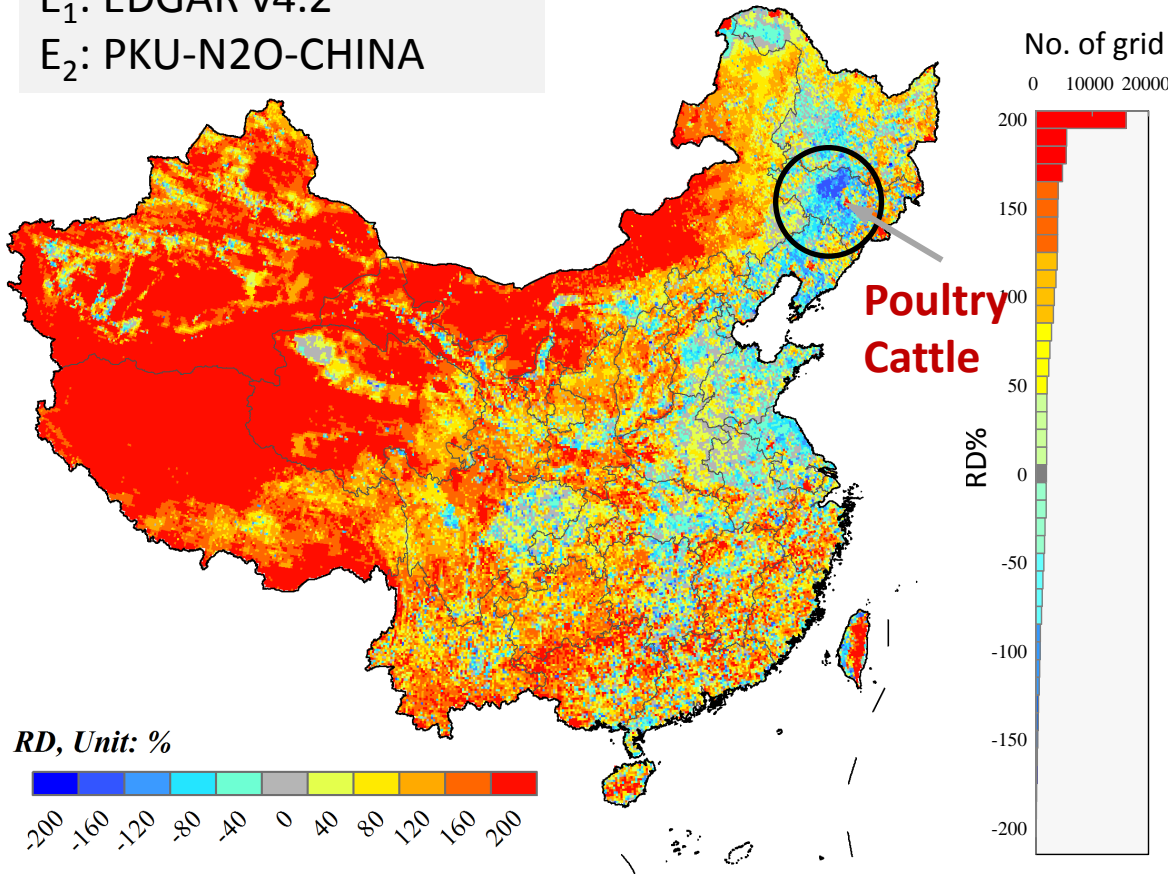

# 4. N<sub>2</sub>O spatial pattern in 2008

- Comparison with EDGARS at 0.1°×0.1° resolution

$$RD = 0.5(E_1 - E_2) / (E_1 + E_2)$$

E<sub>1</sub>: EDGAR v4.2

E<sub>2</sub>: PKU-N2O-CHINA

**average absolute RD:**

121%

**absolute RD > 100%:**

64% of total grids

larger positive RDs  
were found in the  
lower-emission regions

larger negative RDs  
in higher-emission

Implication: mitigation strategies focus on fewer regions but achieve reduction targets

# 5. N<sub>2</sub>O temporal trends

- (2.7% yr<sup>-1</sup>, 1978-1984) → (5.8% yr<sup>-1</sup>, 1985-1996)  
 → (1% yr<sup>-1</sup>, 1997 to 2002)

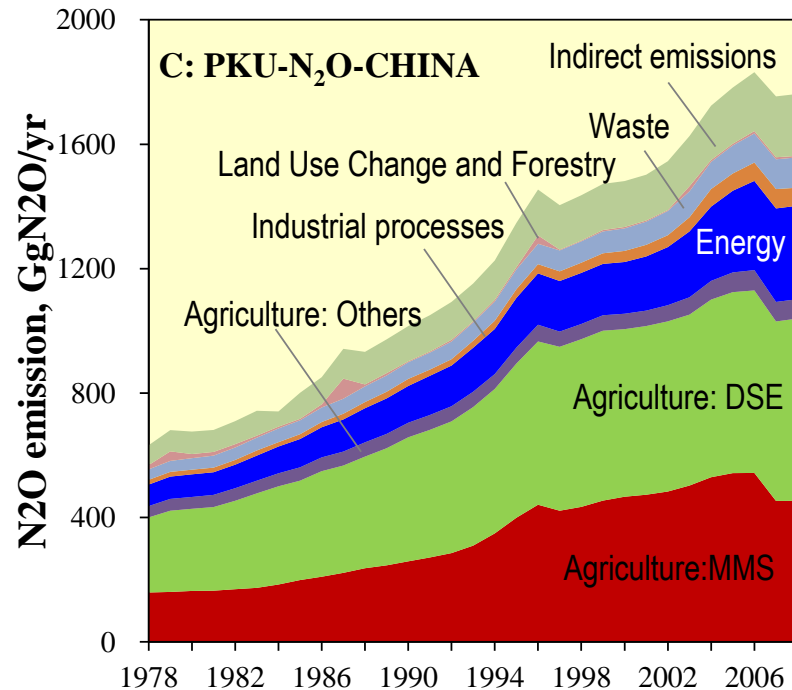

5~20% smaller before 1992 but 0.3%~7% higher than EDGAR v4.2

per hectare cereal yield ↑, N use (117-470) ↑,  
 partial factor productivity (31-12kg/kg) ↓

# 5. N<sub>2</sub>O temporal trends

- Comparisons on source profile

- MMS and energy are higher consistently than EDGAR
- Industrial, indirect are significantly lower

# 6. Implications

## Total emissions

## per capita emissions

- largest source of N<sub>2</sub>O emissions and maintaining a positive increasing trend
- economic structure and lifestyle of new urban residents stimulated the increase of food and energy consumptions

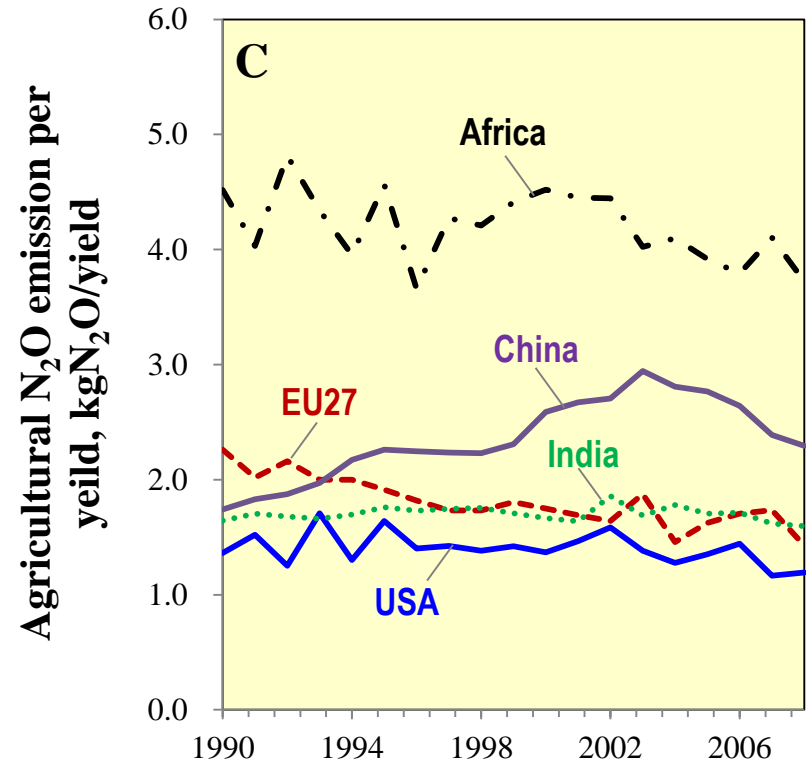

# 6. Implications

per GDP emissions

2.32 g N<sub>2</sub>O·dollar<sup>-1</sup> to 0.37 g N<sub>2</sub>O·dollar<sup>-1</sup>  
half or a quarter of Indian or African

Agricultural  
emissions per yield

1.7 kg·t<sup>-1</sup> in 1978, ↑ 2.9, ↓ 2.3 in 2008

- Requirement of nutrient management, anaerobic digester for MMS, human dietary shift

## 7. Remarks for next step

- Comparison with inverse modeling?
- Estimating effects of  $\text{N}_2\text{O}$  emissions on climate forcing?
- Understanding the drivers of  $\text{N}_2\text{O}$  emissions regionally using Kaya identity?
- Modeling  $\text{N}_2\text{O}$  emissions by OCHIDEE?
- With  $\text{NH}_3+\text{NO}_x$  emissions, estimating effects of N-related emissions on ozone destructions and N deposition?
